## First observation of the decay $B^+ \rightarrow ^{++-}$

LHCb Collaboration ; Bernet, R ; Büchler-Germann, A ; Bursche, A ; Chiapolini, N ; De Cian, M ;  
Elsasser, C ; Müller, K ; Salzmann, C ; Serra, N ; Steinkamp, O ; Straumann, U ; Tobin, M ; Vollhardt,  
A ; Anderson, J

Abstract: A discovery of the rare decay  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  is presented. This decay is observed for the first time, with  $5.2 \sigma$  significance. The observation is made using  $pp$  collision data, corresponding to an integrated luminosity of  $1.0 \text{ fb}^{-1}$ , collected with the LHCb detector. The measured branching fraction is  $(2.3 \pm 0.6 \text{ (stat.)} \pm 0.1 \text{ (syst.)}) \times 10^{-8}$ , and the ratio of the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow ^+ \mu^+ \mu^-$  branching fractions is measured to be  $0.053 \pm 0.014 \text{ (stat.)} \pm 0.001 \text{ (syst.)}$ .

# First observation of the decay $B^+ \rightarrow \pi^+ \mu^+ \mu^-$

The LHCb collaboration<sup>†</sup>

## Abstract

A discovery of the rare decay  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  is presented. This decay is observed for the first time, with  $5.2 \sigma$  significance. The observation is made using  $pp$  collision data, corresponding to an integrated luminosity of  $1.0 \text{ fb}^{-1}$ , collected with the LHCb detector. The measured branching fraction is  $(2.3 \pm 0.6 \text{ (stat.)} \pm 0.1 \text{ (syst.)}) \times 10^{-8}$ , and the ratio of the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  branching fractions is measured to be  $0.053 \pm 0.014 \text{ (stat.)} \pm 0.001 \text{ (syst.)}$ .

# 1 Introduction

The ratio of Cabibbo-Kobayshi-Maskawa matrix [1] elements  $|V_{td}|/|V_{ts}|$  has been measured in  $B$  mixing processes, where it is probed in box diagrams through the ratio of  $B^0$  and  $B_s^0$  mixing frequencies [2–5]. The ratio of these matrix elements has also been measured using the ratio of branching fractions of  $b \rightarrow s\gamma$  and  $b \rightarrow d\gamma$  decays, where radiative penguin diagrams mediate the transition [6–8]. These measurements of  $|V_{td}|/|V_{ts}|$  are consistent, within the (dominant)  $\sim 10\%$  uncertainty on the determination from radiative decays. The decays  $b \rightarrow s\mu^+\mu^-$  and  $b \rightarrow d\mu^+\mu^-$  offer an alternative way of measuring  $|V_{td}|/|V_{ts}|$  which is sensitive to different classes of operators than the radiative decay modes [9]. These  $b \rightarrow (s, d)\mu^+\mu^-$  transitions are flavour-changing neutral current processes which are forbidden at tree level in the Standard Model (SM). In the SM, the branching fractions for  $b \rightarrow d\ell^+\ell^-$  transitions are suppressed relative to  $b \rightarrow s\ell^+\ell^-$  processes by the ratio  $|V_{td}|^2/|V_{ts}|^2$ . This suppression does not necessarily apply to models beyond the SM, and  $B^+ \rightarrow \pi^+\mu^+\mu^-$  decays<sup>1</sup> may be more sensitive to the effect of new particles than  $B^+ \rightarrow K^+\mu^+\mu^-$  decays. In the SM, the ratio of branching fractions for these exclusive modes

$$R \equiv \mathcal{B}(B^+ \rightarrow \pi^+\mu^+\mu^-) / \mathcal{B}(B^+ \rightarrow K^+\mu^+\mu^-) \quad (1)$$

is given by  $R = V^2 f^2$ , where  $V = |V_{td}|/|V_{ts}|$  and  $f$  is the ratio of the relevant form factors and Wilson coefficients, integrated over the relevant phase space. A difference between the measured value of  $R$  and  $V^2 f^2$  would indicate a deviation from the minimal flavour violation hypothesis [10, 11], and would rule out certain approximate flavour symmetry models [12].

No  $b \rightarrow d\ell^+\ell^-$  transitions have previously been detected, and the observation of the  $B^+ \rightarrow \pi^+\mu^+\mu^-$  decay would therefore be the first time such a process has been seen. The predicted SM branching fraction for  $B^+ \rightarrow \pi^+\mu^+\mu^-$  is  $(2.0 \pm 0.2) \times 10^{-8}$  [13]. The most stringent limit to date is  $\mathcal{B}(B^+ \rightarrow \pi^+\mu^+\mu^-) < 6.9 \times 10^{-8}$  at 90% confidence level [14]. The analogous  $b \rightarrow s\ell^+\ell^-$  decay,  $B^+ \rightarrow K^+\mu^+\mu^-$ , has been observed with a branching fraction of  $(4.36 \pm 0.15 \pm 0.18) \times 10^{-7}$  [15].

This paper describes the search for the  $B^+ \rightarrow \pi^+\mu^+\mu^-$  decay using  $pp$  collision data, corresponding to an integrated luminosity of  $1.0 \text{ fb}^{-1}$ , collected with the LHCb detector. The  $B^+ \rightarrow \pi^+\mu^+\mu^-$  branching fraction is measured with respect to that of  $B^+ \rightarrow J/\psi(\rightarrow \mu^+\mu^-)K^+$ , and the ratio of  $B^+ \rightarrow \pi^+\mu^+\mu^-$  and  $B^+ \rightarrow K^+\mu^+\mu^-$  branching fractions is also determined.

The LHCb detector [16] is a single-arm forward spectrometer covering the pseudo-rapidity range  $2 < \eta < 5$ . The experiment is designed for the study of particles containing  $b$  or  $c$  quarks. The apparatus includes a high precision tracking system, consisting of a silicon-strip vertex detector surrounding the  $pp$  interaction region, and a large-area silicon-strip detector located upstream of a dipole magnet. The dipole magnet has a bending power of about 4 Tm. Three stations of silicon-strip detectors and straw drift-tubes are placed downstream of the magnet. The combined tracking system has a momentum resolution

---

<sup>1</sup>Charge conjugation is implicit throughout this paper.

40  $\Delta p/p$  that varies from 0.4% at momenta of 5 GeV/c, to 0.6% at 100 GeV/c. The tracking  
 41 system gives an impact parameter resolution of 20  $\mu\text{m}$  for tracks with a high transverse  
 42 momentum ( $p_T$ ). Charged hadrons are identified using two ring-imaging Cherenkov  
 43 detectors. Photon, electron and hadron candidates are identified by a calorimeter system  
 44 consisting of scintillating-pad and preshower detectors, an electromagnetic calorimeter and  
 45 a hadronic calorimeter. Muons are identified by a system composed of alternating layers  
 46 of iron and either multi-wire proportional chambers or triple gaseous electron multipliers.

47 In the present analysis, events are first required to have passed a hardware trigger  
 48 which selects high- $p_T$  single muons or dimuons. In the first stage of the subsequent software  
 49 trigger, a single high impact parameter and high- $p_T$  track is required. In the second stage  
 50 of the software trigger, events are reconstructed and then selected for storage based on  
 51 either the (partially) reconstructed  $B$  candidate or the dimuon candidate [17, 18].

52 To produce simulated samples of signal and background decays,  $pp$  collisions are  
 53 generated using PYTHIA 6.4 [19] with a specific LHCb configuration [20]. Decays of  
 54 hadronic particles are described by the EVTGEN package [21] in which final state radiation  
 55 is generated using PHOTOS [22]. The interaction of the generated particles with the  
 56 detector and the detector response are implemented using the GEANT4 toolkit [23], as  
 57 described in Ref. [24].

58 The small branching fractions of the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  signal decays  
 59 necessitate good control of the backgrounds and the use of suitably constrained models to  
 60 fit the invariant-mass distributions. The decay  $B^+ \rightarrow J/\psi (\rightarrow \mu^+ \mu^-) K^+$  (hereafter denoted  
 61  $B^+ \rightarrow J/\psi K^+$ ) is used to extract both the shape of the signal mass peaks and, in the  
 62  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  case, the invariant mass distribution of the misidentified  $B^+ \rightarrow K^+ \mu^+ \mu^-$   
 63 events. These misidentified  $B^+ \rightarrow K^+ \mu^+ \mu^-$  events form the main residual background  
 64 after the application of the selection requirements.

## 65 2 Event selection

66 The  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  candidates are selected by combining pairs of  
 67 oppositely charged muons with a charged pion or kaon. The selection includes requirements  
 68 on the impact parameters of the final-state particles and  $B$  candidate, the vertex quality  
 69 and displacement of the  $B$  candidate, particle identification (PID) requirements on the  
 70 muons and a requirement that the  $B$  candidate momentum vector points to one of the  
 71 primary vertices in the event. The rate of events containing more than one reconstructed  
 72 candidate is 1 in  $\sim 20,000$  for  $B^+ \rightarrow J/\psi K^+$ . No restriction is therefore placed on the  
 73 number of candidates per event.

74 The pion identification requirements select a sample of pions with an efficiency of  $\sim 70\%$   
 75 and a kaon rejection of 99%. The kaon identification requirements allow the selection of a  
 76 mutually exclusive sample with similar efficiencies. The muon identification requirements  
 77 have an efficiency of  $\sim 80\%$ , with a pion rejection of  $\sim 99.5\%$ . The PID requirements have  
 78 a momentum dependent efficiency which is measured from data, in bins of momentum,  
 79 pseudorapidity and track multiplicity. The efficiency of the hadron PID requirements is

80 measured from a sample of  $D^{*+} \rightarrow (D^0 \rightarrow K^- \pi^+) \pi^+$  candidates that allows the hadrons  
 81 to be unambiguously identified based on their kinematics. The muon PID efficiencies are  
 82 measured using  $B^+ \rightarrow J/\psi K^+$  candidates, using a tag and probe method.

83 The  $J/\psi$  and  $\psi(2S)$  resonances, where  $J/\psi, \psi(2S) \rightarrow \mu^+ \mu^-$ , are excluded using a  
 84 veto on the dimuon mass. This veto has a total width of 200 (150)  $\text{MeV}/c^2$  around the  
 85 nominal  $J/\psi$  ( $\psi(2S)$ ) mass [25], and takes into account the radiative tail of these decays.  
 86 Candidates where the dimuon mass is poorly measured have a correlated mismeasurement  
 87 in the  $h\mu\mu$  mass. The veto therefore includes a component which shifts with  $h\mu\mu$  mass  
 88 to exclude such candidates. Several other backgrounds are considered: combinatorial  
 89 backgrounds, where the particles selected do not originate from a single decay; peaking  
 90 backgrounds, where a single decay is selected but with one or more particles misidentified;  
 91 and partially reconstructed backgrounds, where one or more final-state particles from a  $B$   
 92 decay are not reconstructed. These backgrounds are each described below.

## 93 2.1 Combinatorial backgrounds

94 A boosted decision tree (BDT) [26] which employs the AdaBoost algorithm [27] is used to  
 95 separate signal candidates from the combinatorial background. Kinematic and geometric  
 96 properties of the  $B^+$  candidate and final state particles,  $B^+$  candidate vertex quality and  
 97 final state particle track quality are input variables to the BDT.

98 The BDT is trained on a simulated  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  signal sample, and a background  
 99 sample taken from sidebands in the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  invariant  
 100 mass distributions. These invariant masses are denoted  $M_{\pi^+ \mu^+ \mu^-}$  and  $M_{K^+ \mu^+ \mu^-}$ , re-  
 101 spectively. The background sample consists of 20% of the candidates with  $M_{\pi^+ \mu^+ \mu^-}$  or  
 102  $M_{K^+ \mu^+ \mu^-} > 5500 \text{ MeV}/c^2$ . This sample is not used for any of the subsequent analysis.  
 103 Signal candidates are required to have a BDT output which exceeds a set value. This  
 104 value is determined by simulating an ensemble of datasets with the expected signal and  
 105 background yields, and choosing the cut value which gives the best statistical significance  
 106 for the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  signal yield. The same method is used to select the optimal set  
 107 of PID requirements. The BDT output distribution for simulated  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  events  
 108 and for mass sideband candidates is shown in Fig. 1. A cut on the BDT output  $> 0.325$   
 109 reduces the expected combinatorial background from  $652 \pm 11$  to  $9 \pm 2$  candidates in a  
 110  $\pm 60 \text{ MeV}/c^2$  window around the nominal  $B$  mass, while retaining 68% of signal events.  
 111 Assuming the SM branching fraction and the single event sensitivity defined in Sect. 4,  
 112  $21 \pm 3$   $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  signal events are expected in the data sample.

## 113 2.2 Peaking and partially reconstructed backgrounds

114 Backgrounds from fully reconstructed  $B^+$  decays with one or more misidentified parti-  
 115 cles have a peaking mass structure. After applying the PID requirements, the fraction  
 116 of  $B^+ \rightarrow K^+ \mu^+ \mu^-$  candidates misidentified as  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  is 0.9%, giving a resid-  
 117 ual background expectation of  $6.2 \pm 0.3$  candidates. This expectation is computed by  
 118 weighting  $B^+ \rightarrow K^+ \mu^+ \mu^-$  candidates, isolated using a kaon PID requirement, accord-

Figure 1: BDT output distribution for simulated  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  events (black solid line) and candidates taken from the mass sidebands in the data (red dotted line). Both distributions are normalised to unit area. The vertical line indicates the chosen cut value of 0.325.

ing to the PID efficiency obtained from the  $D^{*+}$  calibration sample. The only other decay found to give a significant peaking background in the search for  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  is  $B^+ \rightarrow \pi^+ \pi^+ \pi^-$ , where both a  $\pi^+$  and a  $\pi^-$  are misidentified as muons. For  $B^+ \rightarrow K^+ \mu^+ \mu^-$  decays, the only significant peaking background is  $B^+ \rightarrow K^+ \pi^+ \pi^-$ , which includes the contribution from  $B^+ \rightarrow \bar{D}^0 (\rightarrow K^+ \pi^-) \pi^+$ . The expected background levels from  $B^+ \rightarrow \pi^+ \pi^+ \pi^-$  ( $B^+ \rightarrow K^+ \pi^+ \pi^-$ ) decays are computed to be  $0.39 \pm 0.04$  ( $1.56 \pm 0.16$ ) residual background candidates, using simulated events.

Backgrounds from decays that have one or more final state particles which are not reconstructed have a mass below the nominal  $B$  mass, and do not extend into the signal window. However, in the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  case, these backgrounds overlap with the misidentified  $B^+ \rightarrow K^+ \mu^+ \mu^-$  component described above, and must therefore be included in the fit. In the  $B^+ \rightarrow K^+ \mu^+ \mu^-$  case such partially reconstructed backgrounds are negligible.

## 2.3 Control channels

The  $B^+ \rightarrow J/\psi K^+$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  decay candidates are isolated by replacing the pion PID criteria with a requirement to select kaons. In addition, instead of the dimuon mass vetoes described above, the  $B^+ \rightarrow J/\psi K^+$  candidates are required to have dimuon mass within  $\pm 50$  MeV/ $c^2$  of the nominal  $J/\psi$  mass (the  $J/\psi$  mass resolution is 14.5 MeV/ $c^2$ ). The remainder of the selection is the same as that used for  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$ . This minimises the systematic uncertainty on the ratio of branching fractions, although the selection is considerably tighter than that which would give the lowest statistical uncertainty

on the  $B^+ \rightarrow K^+ \mu^+ \mu^-$  event yield. The  $B^+ \rightarrow (J/\psi \rightarrow \mu^+ \mu^-) \pi^+$  candidates (denoted  $B^+ \rightarrow J/\psi \pi^+$ ), which are discussed below, are selected using the same BDT, the pion PID criteria, and the above window on the dimuon invariant mass. There is no significant peaking background for  $B^+ \rightarrow J/\psi K^+$  decays. For  $B^+ \rightarrow J/\psi \pi^+$  decays the only significant peaking background is misidentified  $B^+ \rightarrow J/\psi K^+$  events.

### 3 Signal yield determination

The  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$ ,  $B^+ \rightarrow K^+ \mu^+ \mu^-$  and  $B^+ \rightarrow J/\psi K^+$  yields are determined from a simultaneous unbinned maximum likelihood fit to four invariant mass distributions which contain:

1. Reconstructed  $B^+ \rightarrow J/\psi K^+$  candidates;
2. Reconstructed  $B^+ \rightarrow J/\psi K^+$  candidates, with the kaon attributed to have the pion mass;
3. Reconstructed  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  candidates; and
4. Reconstructed  $B^+ \rightarrow K^+ \mu^+ \mu^-$  candidates.

The signal probability density functions (PDFs) for the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$ ,  $B^+ \rightarrow K^+ \mu^+ \mu^-$ , and  $B^+ \rightarrow J/\psi K^+$  decay modes are modelled with the sum of two Gaussian functions. The PDFs for all of these decay modes share the same mean, widths and fraction of the total PDF between the two Gaussians. The  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  PDF is adjusted for the difference between the widths of the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow J/\psi K^+$  distributions, which is observed to be at the percent level in simulation. The peaking backgrounds described in Sect. 2.2 are taken into account in the fit by including PDFs with shapes determined from simulation. The combinatorial backgrounds are modelled with a single exponential PDF, with the exponent allowed to vary independently for each distribution. The partially reconstructed candidates are modelled using a PDF consisting of an exponential distribution cut-off at a threshold mass, with the transition smeared by the experimental resolution. The shape parameters are again allowed to vary independently for each distribution. The misidentified  $B^+ \rightarrow J/\psi K^+$  candidates are modelled with a Crystal Ball function [28], as it describes the shape well. In order to describe the relevant background components for  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$ , the fit is performed in the mass range  $4900 < M_{\pi^+ \mu^+ \mu^-} < 7000$  MeV/ $c^2$ . To avoid fitting the partially reconstructed background for  $B^+ \rightarrow K^+ \mu^+ \mu^-$ , which is irrelevant for the analysis, the fit is performed in the mass range  $5170 < M_{K^+ \mu^+ \mu^-} < 7000$  MeV/ $c^2$ .

#### 3.1 Reconstructed $B^+ \rightarrow J/\psi K^+$ candidates

The reconstructed  $B^+ \rightarrow J/\psi K^+$  candidates are shown in the  $M_{K^+ \mu^+ \mu^-}$  distribution in Fig. 2(a). The fitted  $B^+ \rightarrow J/\psi K^+$  yield is  $106,230 \pm 330$ . This large event yield determines the lineshape for the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  signal distributions, and provides the normalisation for the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  branching fraction.

Figure 2: Invariant mass distribution for  $B^+ \rightarrow J/\psi K^+$  candidates under the (a)  $K^+ \mu^+ \mu^-$  and (b)  $\pi^+ \mu^+ \mu^-$  mass hypotheses with the fit projections overlaid. In the legend, “part. reco” refers to partially reconstructed background. The fit models are described in the text.

### 3.2 Reconstructed $B^+ \rightarrow J/\psi K^+$ candidates with the pion mass hypothesis

The  $B^+ \rightarrow J/\psi K^+$  candidates reconstructed under the pion mass hypothesis provide the lineshape for the misidentified  $B^+ \rightarrow K^+ \mu^+ \mu^-$  candidates that are a background to the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  signal. The equivalent background from  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  in the  $B^+ \rightarrow K^+ \mu^+ \mu^-$  sample is negligible.

The PID requirements used in the selection have a momentum dependent efficiency and therefore change the mass distribution of any backgrounds with candidates that have misidentified particles. In order to correct for this effect, the  $B^+ \rightarrow J/\psi K^+$  candidates are reweighted according to the PID efficiencies derived from data, as described in Sect. 2.2. This adjusts the  $B^+ \rightarrow J/\psi K^+$  invariant mass distribution to remove the effect of the kaon PID requirement used to isolate  $B^+ \rightarrow J/\psi K^+$ , and to reproduce the effect of the pion PID requirement used to isolate  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$ . In addition, there is a difference in the lineshapes of the  $B^+ \rightarrow J/\psi K^+$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  invariant mass distributions under the pion mass hypothesis. This effect arises from the differences between the two decay modes’ dimuon energy and hadron momentum spectra, and is therefore corrected by reweighting  $B^+ \rightarrow J/\psi K^+$  candidates in terms of these variables. The  $M_{\pi^+ \mu^+ \mu^-}$  distribution after both weighting procedures have been applied is shown in Fig. 2(b).

### 3.3 Reconstructed $B^+ \rightarrow \pi^+ \mu^+ \mu^-$ and $B^+ \rightarrow K^+ \mu^+ \mu^-$ candidates

The yield of misidentified  $B^+ \rightarrow K^+ \mu^+ \mu^-$  candidates in the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  invariant mass distribution is constrained to the expectation given in Sect. 2.2. Performing the fit without this constraint gives a yield of  $5.6 \pm 6.4$  misidentified  $B^+ \rightarrow K^+ \mu^+ \mu^-$  candidates. The

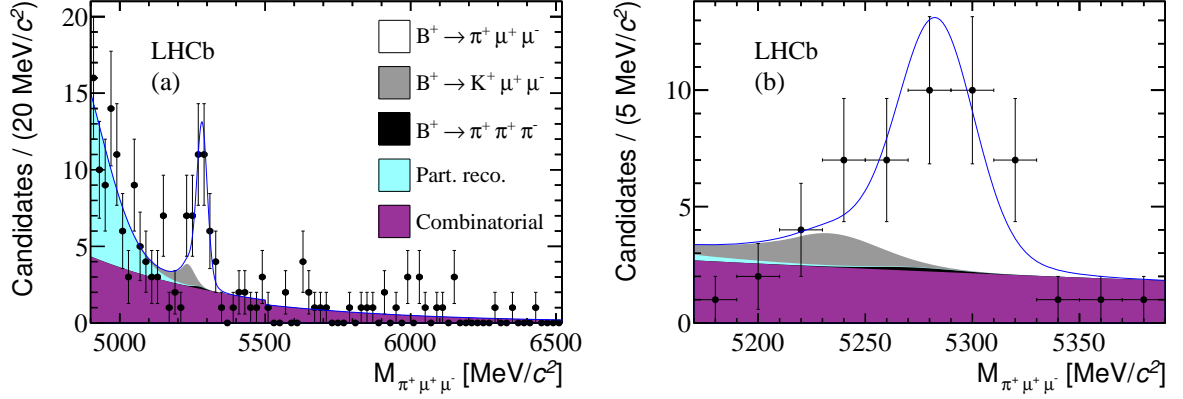

Figure 3: Invariant mass distribution of  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  candidates with the fit projection overlaid (a) in the full mass range and (b) in the region around the  $B$  mass. In the legend, “part. reco.” and “combinatorial” refer to partially reconstructed and combinatorial backgrounds respectively. The discontinuity at 5500  $\text{MeV}/c^2$  is due to the removal of data used for training the BDT.

Figure 4: Invariant mass distribution of  $B^+ \rightarrow K^+ \mu^+ \mu^-$  candidates with the fit projection overlaid (a) in the full mass range and (b) in the region around the  $B$  mass. In the legend, “combinatorial” refers to the combinatorial background.

199 yields for the peaking background components are constrained to the expectations given in  
 200 Sect. 2.2. For both the  $M_{\pi^+ \mu^+ \mu^-}$  and  $M_{K^+ \mu^+ \mu^-}$  distributions, the exponential PDF used  
 201 to model the combinatorial background has a step in the normalisation at 5500  $\text{MeV}/c^2$   
 202 to account for the data used for training the BDT.

203 The  $M_{\pi^+ \mu^+ \mu^-}$  and  $M_{K^+ \mu^+ \mu^-}$  distributions are shown in Figs 3 and 4, respectively. The  
 204 fit gives a  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  signal yield of  $25.3^{+6.7}_{-6.4}$ , and a  $B^+ \rightarrow K^+ \mu^+ \mu^-$  signal yield of  
 205  $553^{+24}_{-25}$ .

Figure 5: Invariant mass distribution of  $B^+ \rightarrow J/\psi \pi^+$  candidates with the fit projection overlaid. In the legend, “part. reco.” and “combinatorial” refer to partially reconstructed and combinatorial backgrounds respectively. The fit model is described in the text.

### 3.4 Cross check of the fit procedure

The fit procedure was cross-checked on  $B^+ \rightarrow J/\psi \pi^+$  decays, accounting for the background from  $B^+ \rightarrow J/\psi K^+$  decays. The resulting fit is shown in Fig. 5. The shape of the combined  $B^+ \rightarrow J/\psi \pi^+$  and  $B^+ \rightarrow J/\psi K^+$  mass distribution is well reproduced. The  $B^+ \rightarrow J/\psi K^+$  yield is not constrained in this fit. The fitted yield of  $1024 \pm 61$  candidates is consistent with the expectation of  $958 \pm 31$  (stat.) candidates. This expectation is again computed by weighting the  $B^+ \rightarrow J/\psi K^+$  candidates, which are isolated using a kaon PID requirement, according to the PID efficiency derived from  $D^{*+} \rightarrow (D^0 \rightarrow K^- \pi^+) \pi^+$  events.

## 4 Determination of branching fractions

The  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  branching fraction is given by

$$\mathcal{B}(B^+ \rightarrow \pi^+ \mu^+ \mu^-) = \frac{\mathcal{B}(B^+ \rightarrow J/\psi K^+)}{N_{B^+ \rightarrow J/\psi K^+}} \frac{\epsilon_{B^+ \rightarrow J/\psi K^+}}{\epsilon_{B^+ \rightarrow \pi^+ \mu^+ \mu^-}} N_{B^+ \rightarrow \pi^+ \mu^+ \mu^-} \quad (2)$$

$$= \alpha \cdot N_{B^+ \rightarrow \pi^+ \mu^+ \mu^-}, \quad (3)$$

where  $\mathcal{B}(X)$ ,  $N_X$  and  $\epsilon_X$  are the branching fraction, the number of events and the total efficiency, respectively, for decay mode  $X$ , and  $\alpha$  is the single event sensitivity. The total efficiency includes reconstruction, trigger and selection efficiencies. The ratio  $\epsilon_{B^+ \rightarrow J/\psi K^+} / \epsilon_{B^+ \rightarrow \pi^+ \mu^+ \mu^-}$  is determined to be  $1.60 \pm 0.01$  using simulated events, where the uncertainty is due to the limited sizes of the simulated samples only. Other sources of systematic uncertainty are discussed in Sect. 5. The difference in efficiencies between  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow J/\psi K^+$  events is largely due to the mass vetoes

used to remove the charmonium resonances, and the different PID requirements. The  $B^+ \rightarrow J/\psi(\rightarrow \mu^+\mu^-)K^+$  branching fraction is  $(6.02 \pm 0.20) \times 10^{-5}$  [25]. Together with the other quantities in Eq. 2, this gives a single event sensitivity of  $\alpha = (9.1 \pm 0.1) \times 10^{-10}$ , where the uncertainty is due to the limited sizes of the simulated samples only.

The ratio of  $B^+ \rightarrow \pi^+\mu^+\mu^-$  and  $B^+ \rightarrow K^+\mu^+\mu^-$  branching fractions is given by

$$R = \frac{N_{B^+ \rightarrow \pi^+\mu^+\mu^-}}{N_{B^+ \rightarrow K^+\mu^+\mu^-}} \frac{\epsilon_{B^+ \rightarrow K^+\mu^+\mu^-}}{\epsilon_{B^+ \rightarrow \pi^+\mu^+\mu^-}}, \quad (4)$$

where simulated events give  $\epsilon_{B^+ \rightarrow K^+\mu^+\mu^-} / \epsilon_{B^+ \rightarrow \pi^+\mu^+\mu^-} = 1.15 \pm 0.01$ .

## 5 Systematic uncertainties

Two sources of systematic uncertainties are considered: those affecting the determination of the  $B^+ \rightarrow \pi^+\mu^+\mu^-$  and  $B^+ \rightarrow K^+\mu^+\mu^-$  signal yields, and those affecting only the normalisation.

Uncertainties in the shape parameters for the misidentified  $B^+ \rightarrow K^+\mu^+\mu^-$  PDF in the fit are taken into account by including Gaussian constraints on their values. The most significant sources of uncertainty in the determination of these shape parameters arise from the procedure for correcting the  $B^+ \rightarrow J/\psi K^+$  mass shape to match that of the  $B^+ \rightarrow K^+\mu^+\mu^-$  decay, and the correction for the hadron PID requirements. The uncertainty on the  $B^+ \rightarrow \pi^+\mu^+\mu^-$  yield determined with the fit takes these shape parameter uncertainties into account, and they are therefore included in the statistical rather than the systematic uncertainty. These uncertainties affect the  $B^+ \rightarrow \pi^+\mu^+\mu^-$  yield at below the one percent level. None of these effects give rise to any significant uncertainty for the  $B^+ \rightarrow K^+\mu^+\mu^-$  decay.

Uncertainties on the two efficiency ratios  $\epsilon_{B^+ \rightarrow J/\psi K^+} / \epsilon_{B^+ \rightarrow \pi^+\mu^+\mu^-}$  and  $\epsilon_{B^+ \rightarrow K^+\mu^+\mu^-} / \epsilon_{B^+ \rightarrow \pi^+\mu^+\mu^-}$  affect the conversion of the  $B^+ \rightarrow \pi^+\mu^+\mu^-$  yield into a branching fraction, and the measurement of the ratio of branching fractions  $R$ . The largest systematic uncertainty on these efficiency ratios is the choice of form factors used to generate the simulated events. Using an alternative set of form factors changes the  $B^+ \rightarrow \pi^+\mu^+\mu^-$  efficiency by 3%, and this difference is taken as a systematic uncertainty. For the ratio of  $B^+ \rightarrow \pi^+\mu^+\mu^-$  and  $B^+ \rightarrow K^+\mu^+\mu^-$ , the alternative form factors are used for both  $B^+ \rightarrow \pi^+\mu^+\mu^-$  and  $B^+ \rightarrow K^+\mu^+\mu^-$ , giving a systematic uncertainty of 1.7%. To estimate the uncertainty arising from the PID efficiency, the ratio of corrected yields between the  $B^+ \rightarrow J/\psi K^+$  and  $B^+ \rightarrow J/\psi \pi^+$  decay modes is measured, varying the PID requirements. The largest resulting difference with respect to the nominal value is 1.1%, which is taken as the systematic uncertainty.

The systematic uncertainty arising from the knowledge of the trigger efficiency is determined using  $B^+ \rightarrow J/\psi K^+$  candidates in the data. Taking the events which pass the trigger independently of the  $B^+ \rightarrow J/\psi K^+$  candidate, the fraction of these events which also pass the trigger based on the  $B^+ \rightarrow J/\psi K^+$  candidate provides a determination of the trigger efficiency. The efficiency determined in this way is compared to that

Table 1: Summary of systematic uncertainties.

Source	$\mathcal{B}(B^+ \rightarrow \pi^+ \mu^+ \mu^-)$ (%)	$\frac{\mathcal{B}(B^+ \rightarrow \pi^+ \mu^+ \mu^-)}{\mathcal{B}(B^+ \rightarrow K^+ \mu^+ \mu^-)}$ (%)
Form factors	3.0	1.7
Trigger efficiency	1.4	1.4
PID performance	1.1	1.1
Data simulation differences	0.4	0.4
Simulation sample size	0.7	0.7
$\mathcal{B}(B^+ \rightarrow J/\psi(\rightarrow \mu^+ \mu^-) K^+)$	3.5	—
Total	5.0	2.6

calculated in simulated events using the same method, and the difference is taken as the systematic uncertainty. This gives a 1.4% uncertainty on  $\epsilon_{B^+ \rightarrow J/\psi K^+} / \epsilon_{B^+ \rightarrow \pi^+ \mu^+ \mu^-}$  and  $\epsilon_{B^+ \rightarrow K^+ \mu^+ \mu^-} / \epsilon_{B^+ \rightarrow \pi^+ \mu^+ \mu^-}$ .

For all decays under consideration, there are small differences between the distributions of some reconstructed quantities in the data and in the simulated events. These differences are assessed by comparing the distributions of data and simulated events for  $B^+ \rightarrow J/\psi K^+$  candidates. The simulation is corrected to match the data where it disagrees, and the resulting 0.4% difference between the raw and corrected ratio of  $B^+ \rightarrow J/\psi K^+$  and  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  efficiencies is taken as a systematic uncertainty. The statistical uncertainty from the limited simulation sample size is 0.7%. When normalising to  $B^+ \rightarrow J/\psi K^+$ , the measured  $B^+ \rightarrow J/\psi K^+$  and  $J/\psi \rightarrow \mu^+ \mu^-$  branching fractions contribute an uncertainty of 3.5% to the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  branching fraction. The systematic uncertainties are summarised in Table 1.

## 6 Results and conclusion

The statistical significance of the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  signal observed in Fig. 3 is computed from the difference in the minimum log-likelihood between the signal-plus-background and background-only hypotheses. Both the statistical and systematic uncertainties on the shape parameters (which affect the significance) are taken into account. The fitted yield corresponds to an observation of the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  decay with  $5.2 \sigma$  significance. This is the first observation of a  $b \rightarrow d \ell^+ \ell^-$  transition. Normalising the observed signal to the  $B^+ \rightarrow J/\psi K^+$  decay, using the single event sensitivity given in Sect. 4, the branching fraction of the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  decay is measured to be

$$\mathcal{B}(B^+ \rightarrow \pi^+ \mu^+ \mu^-) = (2.3 \pm 0.6 \text{ (stat.)} \pm 0.1 \text{ (syst.)}) \times 10^{-8}.$$

This is compatible with the SM expectation of  $(2.0 \pm 0.2) \times 10^{-8}$  [13]. Given the agreement between the present measurement and the SM prediction, contributions from physics beyond the SM can only modify the  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  branching fraction by a small amount. A significant improvement in the precision of both the experimental measurements and the theoretical prediction will therefore be required to resolve any new physics contributions.

287 Taking the measured  $B^+ \rightarrow K^+ \mu^+ \mu^-$  yield and  $\epsilon_{B^+ \rightarrow K^+ \mu^+ \mu^-} / \epsilon_{B^+ \rightarrow \pi^+ \mu^+ \mu^-}$ , the ratio of  
 288  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  branching fractions is measured to be

$$\frac{\mathcal{B}(B^+ \rightarrow \pi^+ \mu^+ \mu^-)}{\mathcal{B}(B^+ \rightarrow K^+ \mu^+ \mu^-)} = 0.053 \pm 0.014 \text{ (stat.)} \pm 0.001 \text{ (syst.)}.$$

289 In order to extract  $|V_{td}|/|V_{ts}|$  from this ratio of branching fractions, the SM expectation  
 290 for the ratio of  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$  branching fractions is calculated using  
 291 the EVTGEN package [21], which implements the calculation in Ref. [29]. This calculation  
 292 has been updated with the expressions for Wilson coefficients and power corrections from  
 293 Ref. [30], and formulae for the  $q^2$  dependence of these coefficients from Refs. [31, 32].  
 294 Using this calculation, and form factors taken from Ref. [33] (“set II”), the integrated  
 295 ratio of form factors and Wilson coefficients is determined to be  $f = 0.87$ . Neglecting  
 296 theoretical uncertainties, the measured ratio of  $B^+ \rightarrow \pi^+ \mu^+ \mu^-$  and  $B^+ \rightarrow K^+ \mu^+ \mu^-$   
 297 branching fractions then gives

$$|V_{td}|/|V_{ts}| = \frac{1}{f} \sqrt{\frac{\mathcal{B}(B^+ \rightarrow \pi^+ \mu^+ \mu^-)}{\mathcal{B}(B^+ \rightarrow K^+ \mu^+ \mu^-)}} = 0.266 \pm 0.035 \text{ (stat.)} \pm 0.003 \text{ (syst.)},$$

298 which is compatible with previous determinations [5–8]. An additional uncertainty will arise  
 299 from the knowledge of the form factors. As an estimate of the scale of this uncertainty,  
 300 the “set IV” parameters available in Ref. [33] change the value of  $|V_{td}|/|V_{ts}|$  by 5.1%.  
 301 This estimate is unlikely to cover a one sigma range on the form factor uncertainty, and  
 302 does not take into account additional sources of uncertainty beyond the form factors.  
 303 A full theoretical calculation taking into account such additional uncertainties, which  
 304 also accurately determines the uncertainty on the ratio of form factors, would allow a  
 305 determination of  $|V_{td}|/|V_{ts}|$  with comparable precision to that from radiative penguin  
 306 decays.

## 307 Acknowledgements

308 We express our gratitude to our colleagues in the CERN accelerator departments for the  
 309 excellent performance of the LHC. We thank the technical and administrative staff at  
 310 CERN and at the LHCb institutes, and acknowledge support from the National Agencies:  
 311 CAPES, CNPq, FAPERJ and FINEP (Brazil); CERN; NSFC (China); CNRS/IN2P3  
 312 (France); BMBF, DFG, HGF and MPG (Germany); SFI (Ireland); INFN (Italy); FOM  
 313 and NWO (The Netherlands); SCSR (Poland); ANCS (Romania); MinES of Russia  
 314 and Rosatom (Russia); MICINN, XuntaGal and GENCAT (Spain); SNSF and SER  
 315 (Switzerland); NAS Ukraine (Ukraine); STFC (United Kingdom); NSF (USA). We also  
 316 acknowledge the support received from the ERC under FP7 and the Region Auvergne.
